# Today's Roadmap

#### Probability Review

- Random variables and realizations
- Conditional probability and Bayes' Rule
- Means, variances and other moments
- Conditional moments
- O Statistics Review
  - The Law of Large Numbers
  - The Central Limit Theorem
  - Hypothesis Testing
  - Example: Testing the means of two RVs
- Linear Algebra Review (very basic)
  - Matrix and vector notation
  - Transposes and inverses
  - Matrix multiplication
  - Matrix "calculus"

## **Probability Review**

イロト イボト イヨト イヨ

To discuss probability we first need a few basic definitions:

- An outcome is something we can observe but may not know in advance *Example:* For a coin flip, H (heads) is an outcome Example: The wage of a randomly sampled worker
- A sample space is a set of all possible outcomes *Example:* For a coin flip,  $\{H, T\}$  is the sample space *Example:* For two coin flips, {*HH*, *HT*, *TH*, *TT*} is the sample space

#### An event is any subset of the sample space

*Example:* For two coin flips,  $\{HH, TT\}$  is the event "getting the same side both times"

• A **probability** is a function from S to [0, 1] such that

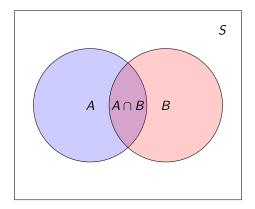

**1** 
$$P(E) \in [0, 1]$$
 for any event,  $E$ 

**2** 
$$P(S) =$$

P(S) = 1
P(A \cup B) = P(A) + P(B) whenever A \cap B = Ø

・ロン ・四 と ・ ヨ と ・ ヨ

#### Outcomes and Events as a Venn Diagram

- A and B are events in the sample space, S
- The intersection, AB, is the purple part
- The union,  $A \cup B$ , would be everything that isn't white

Paul T. Scott NYU Stern

L2 - Math and Statistics Review

# Conditional Probability

• The **conditional probability** of an event, *A*, given, *B*, is the probability that *A* occurs if *B* is known to have occurred.

*Example:* If two dice are rolled and sum to 8, what is the probability at least one dice was a 4?

- How to calculate conditional probability?
  - The new sample space is just B and the event of both A and B happening is AB so a natural definition is:

$$P(A|B) = rac{P(AB)}{P(B)}$$

Notice that we can do the symmetric thing for P(B|A) and rearrange to get Bayes' Rule:

$$P(A|B)P(B) = P(B|A)P(A)$$

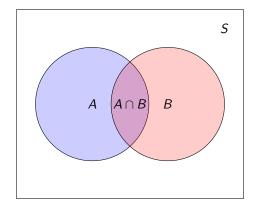

• Real world example: Amartya Sen, "missing women," and sex ratios across the developed and developing world

Paul T. Scott NYU Stern

Fall 2018 6 / 53

(日)

# Conditional Probability in a Venn Diagram

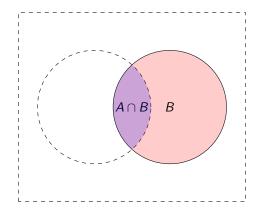

- The probability of A is the relative area of A
- But what if *B* definitely occurred?

Paul T. Scott NYU Stern

Fall 2018 7 / 53

## Conditional Probability in a Venn Diagram

- The probability of A is STILL the relative area of A
- But we only take into account the part of A "inside" B

Paul T. Scott NYU Stern

Fall 2018 7 / 53

- An important definition: A and B are **independent** if P(A|B) = P(A) and vice versa
- Intuitively, independence means that B contains no information about A
- Example: Whether a coin lands heads or tails does not depend on the outcome of any prior flip.
- Is this concept obvious? *Gambler's Ruin*: people observed a roulette wheel turn up black several times and began to bet against black even though each new spin did not depend on the outcome of the previous spin!

#### Random Variables

• A random variable is any function from the sample space S to the real numbers,  $\mathbb R$ 

*Example:* If rolling two dice, the sum is a random variable *Example:* ... so is the number than comes up on one die

- We can easily extend the definition of probability to random variables:
  - ► The probability a random variable X is equal to x is the probability of all events so that X(E) = x. Formally:

$$P(X = x) = P\left(\bigcup_{E:X(E)=x} E\right)$$

Example: If rolling two dice, probability of the sum being 12 is given by:

$$P(D_1 + D_2 = 12) = P(D_1 = 6 \cap D_2 = 6) = 1/36$$

*Example:* If you measure 100 randomly selected men's heights, the average height is a random variable.

Paul T. Scott NYU Stern

Fall 2018 9 / 53

# Discrete versus Continuous Random Variables

Intuition for probability is usually discrete (dice rolls) but a lot of randomness is best modeled as continuous (height or wages)...

- For a continuous random variable X the probability that X = x is "0" since any one outcome happens with vanishingly small probability
- Instead we think about sets like P(a < X < b)
- Define the **Cumulative Distribution Function** of X to be:

$$F(x) = P(X \leq x)$$

• The continuous analog of probability for single events is the **Probability Density Function**:

$$f(x) = \frac{d}{dx}F(x)$$

- This is not the probability of observing x
- It can be bigger than 1!
- However, it acts like a probability in that it is a "weight"

Paul T. Scott NYU Stern

L2 - Math and Statistics Review

Often we do not care about RVs per se but about certain properties:

- The Mean or Expectation of a random variable is the probability-weighted average outcome (denoted by *E*(*X*) or μ<sub>X</sub>)
  - For discrete RVs:

$$E(X) = \sum_{x} P(X = x) * x$$

For continuous RVs:

$$E(X) = \int x f(x) dx$$

• We can easily take the mean of *functions* of random variables:

$$E(g(X)) = \sum_{x} P(X = x)g(x)$$

Paul T. Scott NYU Stern

## Properties of Expectations

• Mean of a constant is a constant:

$$E(a) = a$$

• Linearity:

$$E(aX+bY)=aE(X)+bE(Y)$$

• NOT A Property: Swapping expectations and functions!

$$E(g(X))\neq g(E(X))$$

• Knowledge check: is it true that E(XY) = E(X)E(Y)?

< 🗇 🕨 < 🖻 🕨 < 🖻

# Variance and Covariance

• The Variance of a random variable is defined as follows:

$$Var(X) = E\left((X - E(X))^2\right)$$

This is a measure of the dispersion of X Also denoted by  $\sigma_X^2$ 

• The **Covariance** of two random variables is defined as follows:

$$Cov(X, Y) = E\left((X - E(X))(Y - E(Y))\right)$$

Measure of the tendency of X and Y to move in the same direction

- ► If X and Y tend to be far from the mean at the same time then Covariance has large magnitude
- ▶ If X and Y tend to be large at the same time then Cov will be positive
- ▶ If X tends to be large when Y is small then Cov will be negative

Paul T. Scott NYU Stern

- NB: The covariance and variance of random variables are two of the most important and commonly seen concepts in econometrics! Learn them!
- Useful properties:

$$Cov(aX + bY, Z) = a \times Cov(X, Z) + b \times Cov(Y, Z)$$
  
 $Cov(X, X) = Var(X)$   
 $Var(aX + bY) = a^2 \times Var(X) + b^2 \times Var(Y) + 2ab \times Cov(X, Y)$ 

• Exercise you should have done before: Prove the above!

# Conditional Mean (or Conditional Expectation)

- Conditional mean: expected value of RV, X, if event, A, is known Example: Expected value of a dice roll, D, if we know that D ≥ 4
- The Conditional Mean of a discrete random variable is given by:

$$E(X|A) = \sum_{x} P(X = x|A) * x$$

and analogously for continuous random variables. *Example:* (From above):

$$E(D|D \ge 4) = 4 \times \frac{1}{3} + 5 \times \frac{1}{3} + 6 \times \frac{1}{3} = 5$$

• The conditional mean is also linear but *treats known entities as constant Example:* 

$$E(Y \times X | Y = y) = y \times E(X | Y = y)$$

Paul T. Scott NYU Stern

• The Conditional Variance of a random variable is given by:

$$Var(X|A) = E\left((X - E(X|A))^2|A\right)$$

 Conditional variance has the same properties as variance but also treats constant as known:

$$Var(X \times Y | Y = y) = y^2 \times Var(X | Y = y)$$

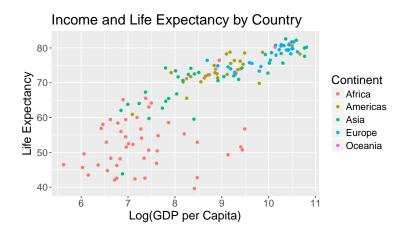

• With two random variables, can define the Conditional Covariance:

$$Cov(X, Y|E) = E\left((X - E(X|A))(Y - E(Y|A))|A\right)$$

Paul T. Scott NYU Stern

Fall 2018 16 / 53

# Conditional Variance: Real World Example

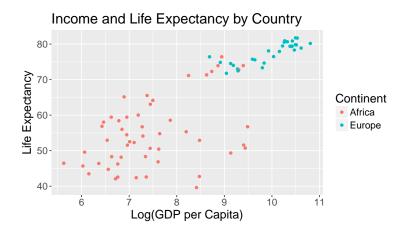

- There's clearly some upward correlation between income and health
- But how does this relationship look within continents?

Paul T. Scott NYU Stern

Fall 2018 17 / 53

# Conditional Variance: Real World Example

- The variance in outcomes in Africa is huge while in Europe it's small
- If one only focused on Africa, there is barely any relationship visible

Paul T. Scott NYU Stern

L2 - Math and Statistics Review

Fall 2018 17 / 53

# Facts and Theorems about Conditional Moments

Key Concept: A mean or a variance is a *number*, the conditional mean or conditional variance is a *function*!
 *Example* Consider a dice roll D:

 €(D) = 3.5
 €(D|D ≥ d) is a function of little d!

• Important fact: If X and Y are independent:

E(X|Y) = E(X)

It should be easy to prove this yourself from the definition of the conditional mean.

# Facts and Theorems about Conditional Moments, Cont'd

Key Theorem 1: The Law of Total Expectation:

 $E\left(E(X|A)\right)=E(X)$ 

- In words: The weighted average of conditional means of random variable is just the unconditional mean
- *Example:* Calculating the average SAT score, *S*, of a college student:

• Calculate the mean across all students, E(S):

$$\mu_{SAT} = \frac{1}{N} \times \sum_{EVERYONE} SAT_i$$

**2** Calculate the mean at each university, E(S|U = u) and then take the population-weighted mean at each university, E(E(S|U = u)):

$$\mu_{SAT} = \mu_{SAT,NYU} \times P(NYU) + \mu_{SAT,Columbia} \times P(Columbia) + \dots$$

- 本語 医 本 医 医 一 医

# Law of Total Expectations Example

Group	Mean of X	<b>Probability of</b> G
A	10	.8
В	5	.2
Total	9	1

• The average of X across all groups (9) is the *weighted* average of the mean in each group.

In math:

$$E(E(X|G)) = E(X|G = 1)P(G = 1) + E(X|G = 2)P(G = 2)$$
  
=10 × .8 + 5 × .2  
=9  
=E(X)

Paul T. Scott NYU Stern

• Key Theorem 2: The Law of Total Variance.

$$Var(X) = E(Var(X|A)) + Var(E(X|A))$$

- ► In words: The variance of X is the average variance of X at different outcomes of A and the variance of the mean of X at different values of A
- Example: The variance in income across countries, X, is the average variance of income within countries, Var(X|A) plus the variance of average income between countries, E(X|A)
- Alert: Conditional moments are very important in econometrics

In addition to random variables we can define a sequence of random variables, X<sub>n</sub> as a sequence of functions from an underlying probability space to ℝ

Example: The sum of n dice rolls

- Sequences in calculus have a sense of convergence
- Random variables are more complicated because they are random. There are three types of convergence:
  - Almost Sure Convergence (Not going to use this, just here for completeness)
  - **2** Convergence in Probability
  - **3** Convergence in Distribution

•  $X_n$  is said to converge almost surely to X if for any  $\varepsilon > 0$ 

$$P\left(\lim_{n\to\infty}|X_n-X|<\varepsilon\right)=1$$

• If X is a constant (i.e., just a number),  $\mu$ , then the probability of drawing a sequence  $X_n$  so that  $\lim_{n\to\infty} X_n \neq \mu$  goes to 0

Similar to standard definition: for *any* given sequence, eventually that specific sequence will settle down.

*Example:* Let  $X_n$  be maximum value of dice roll for n throws of dice.  $X_n$  converges almost surely to 6 since the probability of *never* rolling 6 goes to zero

# Convergence in Probability

 X<sub>n</sub> is said to converge in probability to X (or we say X<sub>n</sub> is consistent for X) if for any ε > 0

$$\lim_{n\to\infty}P\left(|X_n-X|>\varepsilon\right)=0$$

- If X is a constant (i.e., just a number), μ, then as n gets large the probability that X<sub>n</sub> ≠ μ becomes 0
- The difference between convergence almost surely and in probability is subtle (and honestly not important for this course)
- Key takeaway: for a random variable, even as *N* gets large, there can be some probability that something crazy happens. Convergence concepts are a mathematical way of saying this probability vanishes.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

• A random variable X<sub>n</sub> converges in distribution to X if the cdfs converge:

$$\lim_{n\to\infty}F_n(x)=F(x)$$

- Intuition: as *n* gets large, *X<sub>n</sub>* is still a random variable (rather than converging to a number), and it behaves like *X* in terms of probabilities of events
- We will visualize this below when reviewing the Central Limit Theorem

#### **Statistics Review**

メロト メポト メヨト メヨト

- We start with a sample of data that consists of a series of observations
- Each ob is a realization of a random variable from an underlying distribution called the **data generating process** or the **population** 
  - If all observations come are independent and come from same distribution, then data is said to be independently and identically distributed (iid)
  - A Simple Random Sample is a set of independent draws from the same distribution, and is guaranteed to yield iid data
- $\bullet$  A Statistic is any function from the data to  $\mathbb R$
- A Parameter is a number that characterizes the population
- Some notation:
  - Index observations with a subscript: so  $X_i$  is  $i^{th}$  observation
  - Represent data as a random variable with a capital letter, X
  - Represent a realization with a lower case letter, x

・ 回 ト ・ ヨ ト ・ ヨ ト

• A random sample itself is a random variable!

- Why: Two different random samples have different numbers, and so are different realizations from the same distribution
- Each observation is also a random variable

*Example:* If a roll a dice 5 times, ONE sample would be  $\{H, H, T, T, H\}$  but another sample could be  $\{H, T, T, H, T\}$ .

• This also means that statistics (functions of the sample) are random variables as well

*Example:* The sample mean  $\bar{X}$  is a random variable *before* data is observed (but a number after)

< 同 > < 三 > < 三 >

Consider a fair coin and labeling heads as 0 and tails as 1.

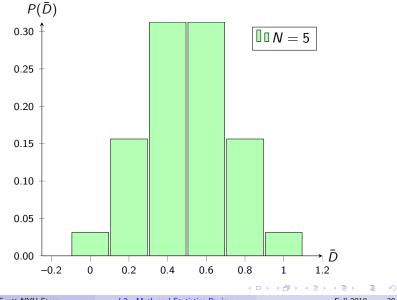

• Calling the dice outcome, D:

$$E(D) = .5 \times 1 + .5 \times 0 = .5$$

- Now consider an experiment of flipping the coin 5 times:
  - For each sample,  $\{D_1, ..., D_5\}$ , calculate  $\overline{D}$
  - Example 1:  $\{H, H, T, T, H\}$  implies  $\overline{D} = .4$
  - Example 2:  $\{T, H, T, T, H\}$  implies  $\overline{D} = .6$
- For different samples, different values of  $\overline{D}$ , so what is the distribution?
  - ► For each possible value of D
     need the probability of all possible flips (events) that yield that value

< 回 > < 三 > < 三 >

# Sample Moments versus Population Moments

• Many statistical models contain some parameter that we wish to estimate

*Examples:* Mean of an RV,  $\mu$ , of the correlation between X and Y,  $\rho_{XY}$ 

- Statistics that estimate parameters are called estimators or estimates
  - The sample mean (or sample variance, etc.) is the mean of the sample. It is an example of a statistic
  - For a sample of data,  $X_1, ..., X_N$  the sample mean is given by,

$$\bar{X} = \frac{1}{N} \sum_{i=1}^{N} X_i$$

- This is NOT the population mean, E(X) (a parameter)
- We often denote an estimator with a "hat":  $\bar{X} = \hat{\mu}$ .

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

- Statistics and estimates do not fall from the sky
- We like or dislike different estimators based on desirable properties and whether they work with our modeling assumptions
- List of useful properties (we'll see these again):
  - **1** Unbiasedness:  $E(\hat{\mu}) = \mu$
  - **2** Consistency:  $\lim_{N\to\infty} \hat{\mu} \xrightarrow{p} \mu$
  - **3** Efficiency: Whether or not  $Var(\hat{\mu}_X)$  is large or small.

Goal of econometrics: find estimators that have as many of these properties fulfilled as we can

# The Power of Large Samples

- $\bar{X}$  matters because it is a good predictor of  $\mu_X$
- In general, we care about statistics that are informative about important parameters of the population

Sample Variance  $\frac{1}{N-1}\sum_{i=1}^{N-1} (X_i - \bar{X})^2 \Leftrightarrow$  Population Variance

Sample Covariance  $\frac{1}{N-1}\sum_{i}(X_i - \bar{X})(Y_i - \bar{Y}) \Leftrightarrow$  Population Covariance

- Theorem: The Law of Large Numbers For a SRS, as the sample size, N, becomes large, the sample mean,  $\bar{X}$  will converge in probability to  $\mu_X$ 
  - $\blacktriangleright$  Some technical conditions are needed for formal proof basically need  $\sigma_X^2 < \infty$
  - Stronger versions of this theorem exist, but above is good enough
  - Corollary: for (most) functions:

$$\frac{1}{N}\sum_{i=1}^{N}f(X_i)\to E(f(X))$$

34 / 53

 The LLN is *hugely* important because it guarantees that sample moments converge to population moments!
 Paul T. Scott NYU Stern
 L2 - Math and Statistics Review
 Fall 2018

### The Central Limit Theorem

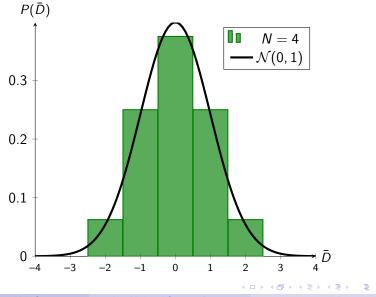

- The LLN says that  $\bar{X}$  will eventually get close to  $\mu_X$ , but how close?
- **Theorem: The Central Limit Theorem** For a sequence of iid variables,  $X_i$ , where  $E(X) = \mu$  and  $Var(X) = \sigma^2$ :

$$\lim_{n\to\infty}\sqrt{n}\times\frac{\bar{X}-\mu}{\sigma}\overset{\text{dist.}}{\to}\mathcal{N}(0,1)$$

- Says that for *n* large, sample means will be approximately normally distributed NO MATTER HOW *X* is DISTIRBUTED
- **NB:** The exercise is treating  $\bar{X}$  as a random variable, so it says that for REPEATED draws of a sample of data, the distribution of the mean across samples will look a certain way.

Paul T. Scott NYU Stern

L2 - Math and Statistics Review

Fall 2018 36 / 53

#### Interlude: The Normal Distribution...

- Normal distribution is the most important in statistics.
- Define the Standard Normal Distribution to be N(0, 1) and denote it by Z. We use Φ for the cdf of Z and φ for the pdf.
- Key Properties:
  - Linearity: If X ~ N(μ<sub>X</sub>, σ<sup>2</sup><sub>X</sub>) and Y ~ N(μ<sub>Y</sub>, σ<sup>2</sup><sub>Y</sub>) are both normal with covariance σ<sub>XY</sub>, then,

$$aX + bY \sim \mathcal{N}\left(a\mu_X + b\mu_Y, a^2\sigma_X^2 + b^2\sigma_Y^2 + 2ab\sigma_{XY}
ight)$$

NB: Any Normal RV has cdf Φ((x − μ)/σ) (called standardizing)
Symmetry about the mean:

$$\Phi\left(\frac{x-\mu}{\sigma}\right) = 1 - \Phi\left(-\frac{x-\mu}{\sigma}\right)$$

Paul T. Scott NYU Stern

▲圖▶ ▲ 国▶ ▲ 国▶

### ... and its Cousins

- A squared standard normal random variable,  $Z^2$  is called a  $\chi^2(1)$  (**chi-squared** of degree 1) random variable
  - ► The sum of q independent \u03c0(1)<sup>2</sup> RVs is a \u03c0<sup>2</sup>(q) random variable. Called "chi-squared with q degrees of freedom"
  - Arises naturally when squaring things like sample means
- If  $Z \sim \mathcal{N}(0, 1)$  is normal and V is  $\chi^2(q)$  then  $Z/\sqrt{V/q}$  is defined as **t-distributed** random variable with q degrees of freedom.
  - Arises naturally in stats whenever sample is drawn from a normal distribution
  - Limit as  $q o \infty$  is normal
- If U follows a t-distribution then  $U^2$  follows an F-distribution

- 本間 ト イヨ ト イヨ ト 三 ヨ

## Hypothesis Testing: Introduction

- Often we are interested in making inference about a sample or samples.
   *Example 1:* Is the mean income in two countries different?
   *Example 2:* Is the mean of a sample greater than some number μ?
- The central issue: data is noisy and random ⇒ two numbers will rarely be *exactly* the same
- **Hypothesis Test:** If we *assume* a specific hypothesis is true, then the likeliness of the observed data is informative about the likeliness of the hypothesis.

Intuition: If a coin is fair, then getting 50 heads in a row is very unlikely  $\Rightarrow$  the coin is probably not fair

*Example:* If a random variable is distributed standard normal Z then observing a number greater 3 than would only happen with .14% probability  $\Rightarrow$  RV is probably *not* standard normal.

くぼう くほう くほう しゅ

- Null Hypothesis: Denoted H<sub>0</sub>. A hypothesis the researcher assumes is true (e.g., μ<sub>X</sub> = 0)
- Alternative Hypothesis: Denoted  $H_a$ . An alternative to the null (e.g.,  $\mu_X \neq 0$ )
- **Test Statistic:** A function of the data that is distributed differently between the null and alternative hypotheses.

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

- $\alpha$ -Level Test: Rejecting the null hypothesis if the test statistic occurs with less than  $\alpha$ % probability under the null.
  - $\blacktriangleright$   $\alpha$  is the Type I error:  $\alpha\%$  of the time, a null will be incorrectly rejected
  - Related concept is **Type II error:** the probability a significant result is treated as null
- In math notation: Given a test statistic, U, with realization u, a two-sided α-level test will reject the null if P(U < u ∪ U > u|H<sub>0</sub>) > α
- One-sided versus Two-sided tests: If we "know" that a parameter has some restrictions (e.g.,  $\mu_X > 0$ ) then we can may only test if u > U but the idea of the test is the same

くぼう くほう くほう しゅ

## An Example: Testing Means

Consider two independent samples,  $X_i$  and  $Y_i$ , of income from different countries and test if the mean income is the same.

• Step 1: Write down the hypotheses:

 $H_0: \mu_X = \mu_Y$  $H_a: \mu_X \neq \mu_Y$ 

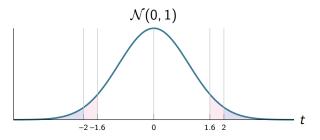

- Step 2: Construct a test statistic.
  - From LLN and CLT: If *n* is large then  $\bar{X}$  is approximately normal. Denoted  $\bar{X} \stackrel{a}{\sim} \mathcal{N}(\mu_X, \sigma^2/n)$
  - Same is true for Y and since Normal RVs are linear:

$$t = \frac{\left(\bar{X} - \bar{Y}\right) - \left(\mu_X - \mu_Y\right)}{\sqrt{\left(\sigma_X^2 + \sigma_Y^2\right)/n}}$$

▶ IF  $H_0$  true THEN  $t \sim^a \mathcal{N}(0, 1)$ 

# An Example: Testing Means (Cont'd)

 $\bullet\,$  Step 3: Choose a level  $\alpha$  and determine critical values of the test

• Step 4: Check if *t* lies outside of the critical region, if so reject the null hypothesis.

*Intuition:* t should only be in the purple region 10% of the time if the null is true. This is unlikely enough that we consider it evidence against the null.

▶ For 10% test, *cv* is 1.65, for 5% tests, *cv* if 1.96

Paul T. Scott NYU Stern

# On standard deviations and standard errors

- Where does the "n" come from in the CLT?
- It represents the fact that the variance of the *estimator* is shrinking as *n* gets big
- Standard error: the standard deviation of the estimator
  - For a sample mean:  $\sigma_{\bar{X}} = \sigma_X / \sqrt{N}$
  - This relates the standard deviation and the standard error
- Often times we don't know  $\sigma_X$  so we have estimate it using:

$$s_X^2 = rac{1}{N-1} \sum_{i=1}^N (X_i - \bar{X})^2$$

- Technicality: Now we have an estimated parameter ( $s_X$  in the denominator, NOT  $\sigma_X$ )
  - Technically need to use a t-distribution with n degrees of freedom, not a normal
  - ▶ Distinction vanishes as *N* gets big (and most data sets have large *N*)
  - We will not dwell on this

Paul T. Scott NYU Stern

# p-Values

A test-statistic carries a lot of information...

- An alternative to doing a test is to report a p-value
- **p-value**: Given the null hypothesis, what is the probability of drawing a value of  $\bar{X}$  at least as far in the tails of the distribution as the observed value of  $\bar{X}$ 
  - Mathematically:

$$p = P\left(\left|\bar{X} - \mu_X\right| > \left|\bar{X}^{data} - \mu_X\right|\right| H_0\right)$$

- In principle this depends on the distribution of  $\bar{X}$
- ▶ With the CLT approximation, for a two-sided p-value:

$$p \approx 2\Phi(-|t|)$$

• p-values are the smallest possible  $\alpha$  test that would reject the null

# Confidence Intervals

Another way to give us the information in a test is to construct a confidence interval:

- Confidence Interval: Given a sample mean, a  $\alpha$ % Cl is a set that contains the population parameter with  $\alpha$ % probability.
- Idea:
  - **1** Pick a random null hypothesis,  $\mu_0$
  - 2 Is this reject by a  $1 \alpha$ -level test?
  - If NO, put it in the confidence interval
  - **(9)** Do this for all possible values of  $\mu_0$
- In other words: a confidence interval is all possible hypotheses that we could not reject at  $\alpha\%$  probability
- In general, also depends on the distribution of  $ar{X}$
- With CLT approximation:

$$CI_{\alpha} = \bar{X} \pm cv_{\alpha} \times \sigma_{\bar{X}}$$

Paul T. Scott NYU Stern

• • = • • = •

What are the main ideas to remember going forward?

- **①** Statistics is about finding parameter estimates with desirable properties
  - Estimates themselves are RVs
  - Properties we like: not being wrong as often as possible
- 2 The tools of the trade boil down to the CLT and the LLN
- Because of randomness, to do inference we need to do hypothesis testing
  - A Hypothesis Test tells us how likely a sample is given a parameter value in the population
  - Many ways to summarize the same info: t-statistic, p-value, Cl

## **Basic Definitions**

- A **vector** in  $\mathbb{R}^n$  is a column of numbers  $(x_1, x_2, ..., x_n)$ .
- A matrix in R<sup>n×m</sup> is m columns of length n vectors (so n is the number of rows and m is the number of columns). We denote an element of a matrix by m<sub>ii</sub> for row i and column j:

$$M = \left(\begin{array}{cc} m_{11} & m_{12} \\ m_{21} & m_{22} \end{array}\right)$$

• For an entity on which there are many pieces of data, we store the data in a vector x<sub>i</sub>

*Example:* For the USA could have  $x_{USA} = (GDP_{USA}, Population_{USA}, ...)$ 

• For many entities we can store all the data in a data matrix, X. Example: For two countries:

$$X = \begin{pmatrix} GDP_{USA} & Population_{USA} \\ GDP_{Canada} & Population_{Canada} \end{pmatrix}$$

• For two vectors of equal length define the dot product as,

$$v \cdot w = \sum_{i=1}^{n} v_i \times w_i$$

• For two matrices, A and B of sizes  $n \times m$  and  $m \times k$  define the **matrix** product C = AB as the  $n \times k$  matrix with entries  $c_{ij} = \sum_{l=1}^{m} a_{il} b_{lj}$ 

- Easy way to remember: (i, j)<sup>th</sup> element of product is dot product of i<sup>th</sup> row and j<sup>th</sup> column of A and B respectively.
- Not all matrices can be multiplied: left matrix must have column length equal to right matrix's row length
- Multiplication is NOT commutative:  $AB \neq BA$  even if they both exist

▲ 御 ▶ ▲ 臣 ▶ ▲ 臣 ▶ ─ 臣

- Define the **transpose** of A as the matrix A' with elements  $a'_{ij} = a_{ji}$  (reverse columns and rows)
- A matrix is symmetric if A' = A
- Important Properties:
  - The matrix B = A'A is *always* a square matrix
  - The matrix B = A'A is always symmetric
  - ► (A')' = A
  - Multiplication Rule: (AB)' = B'A'
  - Addition Rule: (A + B)' = A' + B'

(3)

- The **Identity Matrix**, *I*, is a matrix with 1s on the diagonal and 0s elsewhere. Clearly AI = A.
- Define the **left inverse** of A to be the matrix  $A^{-1}$  such that  $A^{-1}A = I$ 
  - Can analogously define right inverse
  - Right and left inverse will NOT be the same if A is not a square matrix
  - Right and left inverse WILL be equal if A is square (then we just say inverse)
- Important Properties:
  - ▶ Multiplication Rule: (AB)<sup>-1</sup> = B<sup>-1</sup>A<sup>-1</sup>
     ▶ Tranpose Rule: (A')<sup>-1</sup> = (A<sup>-1</sup>)'

  - **Dot Product:**  $v \cdot w = v'w$

 For a function f : ℝ<sup>n</sup> → ℝ<sup>m</sup> recall the definition of the derivative or Jacobian of f:

$$Df = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_m}{x_1} \\ \vdots & & \\ \frac{\partial f_1}{\partial x_n} & \cdots & \frac{\partial f_m}{x_n} \end{pmatrix}$$

- We WON'T be doing anything too complicated! But we can define two important functions given a vector x and a matrix A:
  - For Ax, D(Ax) = A (as a line in 1-D calc)
  - For x'Ax, D(x'Ax) = x'(A + A') (as a quadratic in 1-D calc)
